The Equation of motions

$$m \frac{d^2 x}{dt^2} = F_D + F_L + F_S + mg \quad (1)$$

where

$$F_D = \frac{1}{2} \rho A |\dot{x}|^2 C_D (-\hat{x}) \quad (2)$$

$$F_L = \frac{1}{2} \rho A |\dot{x}|^2 C_L \hat{n} \quad (3)$$

$$F_S = \frac{1}{2} \rho A |\dot{x}|^2 C_S (\hat{n} \times \hat{v}) \quad (4)$$

- ρ is the density of the air, a is the ball radius, ω is the angular velocity
- U is the velocity of the ball, μ is the dynamic air viscosity

If Spin is zero, $C_L = 0$ and $C_S = 0$ The coefficients C_L , C_S and C_D depend on

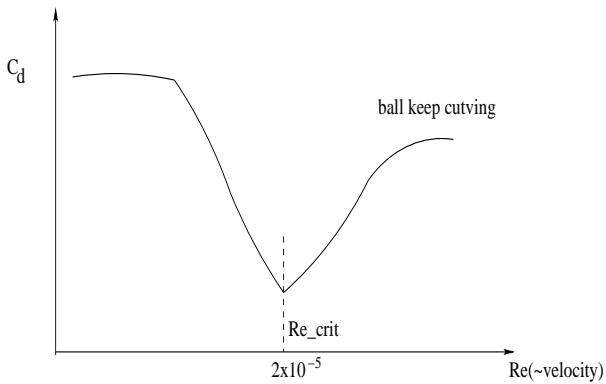

$$Re = \rho \frac{Ua}{\mu} \quad (5)$$

$$Sp = \frac{a\omega}{U} \quad (6)$$

$$Roughness = \frac{k}{a} \quad (7)$$

Top spin $\rightarrow V$

Ball Flight Differential Equation

$$\frac{d^2x}{dt^2} = -v \left(k_d \frac{dx}{dt} - k_l \sin\gamma \frac{dy}{dt} \right)$$

$$\frac{d^2y}{dt^2} = -v \left(k_d \frac{dy}{dt} + k_l \left(\cos\gamma \frac{dz}{dt} + \sin\gamma \frac{dx}{dt} \right) \right)$$

$$\frac{d^2z}{dt^2} = -g - v \left(k_d \frac{dz}{dt} - k_l \cos\gamma \frac{dy}{dt} \right) \quad (8)$$

Dimensional Equation

$$\frac{d^2x}{dt^2} = k_l \sin \gamma \left(\frac{dy}{dt} \right)^2$$

$$\frac{d^2y}{dt^2} = -k_d \left(\frac{dy}{dt} \right)^2$$

$$\frac{d^2z}{dt^2} = -g + k_l \cos \gamma \left(\frac{dy}{dt} \right)^2 \quad (9)$$

with solution

$$y(t) = \frac{1}{k_d} \ln(1 + \dot{y}_0 k_d t) \quad (10)$$

$$x(t) = \dot{x}_0 t - \frac{k_l}{k_d^2} \sin \gamma \ln(1 + \dot{y}_0 k_d t) + \frac{k_l}{k_d} \sin \gamma \dot{y}_0 t \quad (11)$$

$$z(t) = \dot{z}_0 t - \frac{1}{2} g t^2 - \frac{k_l}{k_d} \cos \gamma \ln(1 + \dot{y}_0 k_d t) + \frac{k_l}{k_d} \cos \gamma \dot{y}_0 t \quad (12)$$

By expanding $\ln(1 + k_d \dot{y}_0 t)$ for small $k_d \dot{y}_0 t$ ($k_d \sim 10^{-2}$, $\dot{y}_0 \sim 20$), we have

$$\ln(1 + k_d \dot{y}_0 t) \sim k_d \dot{y}_0 t + \frac{1}{2} k_d^2 \dot{y}_0^2 t^2 \quad (13)$$

Hence, we obtain

$$y(t) = \dot{y}_0 t - k_d \dot{y}_0^2 \frac{t^2}{2} \quad (14)$$

$$x(t) = \dot{x}_0 t + k_l \sin \gamma \dot{y}_0^2 \frac{t^2}{2} \quad (15)$$

$$z(t) = \dot{z}_0 t - \frac{t^2}{2} (g - k_l \cos \gamma \dot{y}_0^2) \quad (16)$$

What use is this?

(or How do I use this knowledge to beat Ajax?)

$$y(t) = \dot{y}_0 t - k_d \dot{y}_0^2 \frac{t^2}{2} \quad (17)$$

$$x(t) = \dot{x}_0 t + k_l \sin \gamma \dot{y}_0^2 \frac{t^2}{2} \quad (18)$$

$$z(t) = \dot{z}_0 t - \frac{t^2}{2} (g - k_l \cos \gamma \dot{y}_0^2) \quad (19)$$

Forward motion depends on k_d, \dot{y}_0

Swerve depends on $k_l, \sin \gamma, \dot{y}_0$

$$k_d = \frac{\rho A C_d}{2m} \quad k_l = \frac{\rho A C_l}{2m} \quad (20)$$

$$C_d = C_d(Re, Sp, Ro) \quad C_l = C_l(Re, Sp, Ro) \quad (21)$$

Difference in ball behaviour between cities

I can kick the ball with a certain amount of spin so how does ball behaviour differ between cities

Motion depends on Re , Ro

Ro accounts for pattern and smoothness

$Re = \rho Ua / \mu - \rho$ varies significantly

$\rho(\text{CT}) \approx 1.29\text{kg/m}^3$ hence Re high

$\rho(\text{JB}) \approx 1.04\text{kg/m}^3$ hence Re low

Drag higher in CT - CT players expect more curve

What ball to use?

When $Re > Re_{crit}$ ball keeps on curving
Increasing Ro decreases Re_{crit}
(Reverse Magnus around Re_{crit} ... Jabulani)

Playing in Jo'burg
T90 is dimpled, so curves best, hence play with smooth ball
(and/or smaller ball)

Playing in CT
Practice with T90 (and/or larger ball) (and hope they choose a
smooth ball)
